

Brainstorm / Sketch

Idea: Elderly reminder / alert device

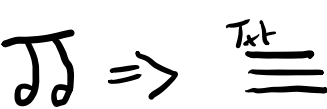

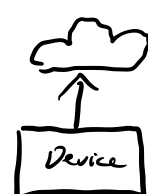

General Description: A device that would allow somebody to record a voice note, this note would then be transcribed to text format. Text is sent to a website so that they can be displayed and accessed by user / family / carer

Selling Points: Product would be for those who are untrustworthy or consistently listening devices such as Amazon Alexas. It is aimed at users who struggle with memory loss as it allows them to record notes or reminders for themselves or a family member / carer etc..
Could also be used as a more advanced tape recorder for creatives who want to record ideas on the go

Wire frame

How it works

- 1) 
 - Device records sound when button pressed using microphone
 - After button is released, recording is saved as a .wav file to the system storage
- 2) 
 - Using AI (google speech to text API), saved (.wav) file is converted from sound to text format (string)
- 3) 
 - Device uploads text string to cloud database along with time and date of recording
- 4) 
 - Website downloads text string, time and date and displays them in a clean, accessible way
